

Supplement 234

DICOMWEB STORAGE COMMITMENT SERVICE

WG27 – WEB SERVICES FOR DICOM

LETTER BALLOT

DIETER KROTZ & JEROEN MEDEMA

AUGUST 2023

Work Item 2022-04-A

Limitations of Current Standard

- DICOMweb covers the classic DICOM Storage and Query/Retrieve services with the same semantics: data is being copied. For DICOMweb the need to be able to rely on the fact that other systems will safely keep copied data safely is also applicable. However, there is no Storage Commitment service in DICOMweb to achieve that; there is an inconsistent set of services in DICOMweb compared to classic DICOM. Solutions will have to fall back to other mechanisms to achieve safekeeping.

Description of the proposal

- Define the Storage Commitment service in DICOMweb given the described safekeeping need.
- It needs to be determined what mechanisms are to be defined/selected for achieving this functionality. Even though Storage Commitment in classic DICOM supports both synchronous and asynchronous approaches, where the latter seems to be deployed more often, this does not necessarily need to be the way this is to be done in a RESTful way. Security aspects and existing non-standard solutions will play a role in determining how to achieve this functionality.

Approved by the DICOM Standards Committee, April 2022; work item 2022-04-A.

Summary (1 of 2)

Supplement 234 – DICOMweb Storage Commitment

- adds one top-level resource for storage commitment: `/commitment-requests`;
 - This mimics the approach taken by DIMSE.
- allows for both synchronous and asynchronous communication utilizing polling;
 - Storage commitment is often a long running process (e.g., a PACS is delegating storage commitment to a VNA and waits for the confirmation of the VNA before agreeing to storage commitment by itself).
 - [See Details – Flow.]
- allows for bi-directional proxyability;
 - Enables hybrid solutions, with both legacy and state-of-the-art systems.
 - [See Details – Proxyability.]
- allows for adding study and series context to the referenced instances;
 - This speeds up finding these instances at the server side.

Summary (2 of 2)

- allows for specifying a 'retry-after time' by the Origin Server;
 - Enables regulated polling, as to manage server load.
- respects the (informal) semantics of HTTP POST and GET.
 - Fits the cloud/RESTful approaches.

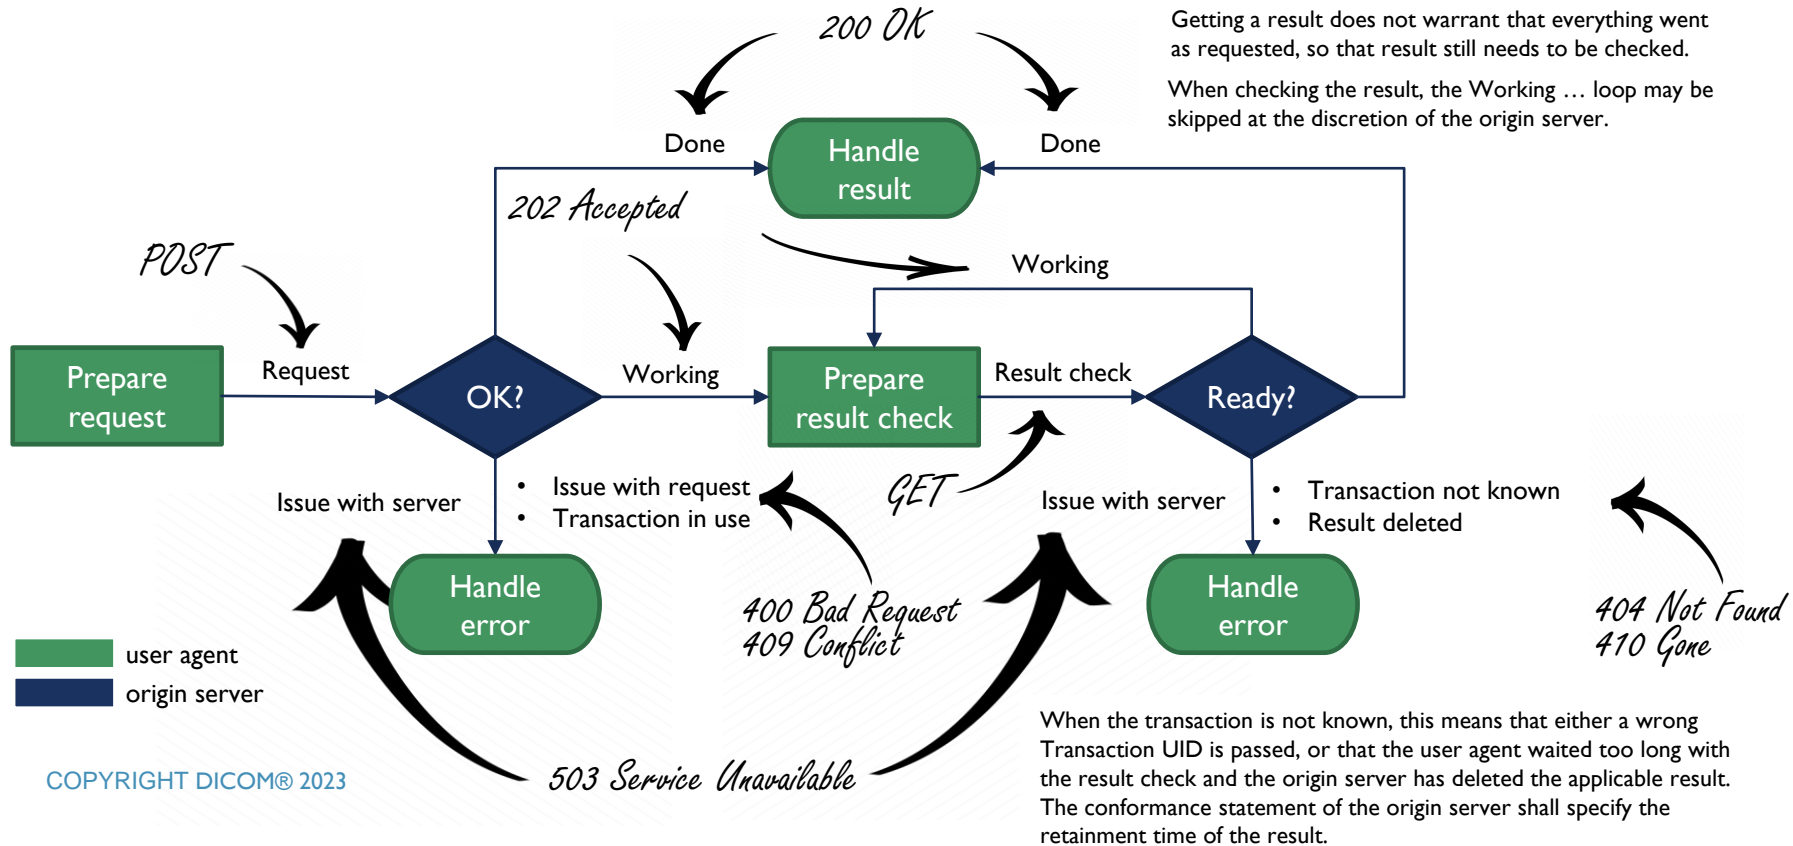

Next to the above, it also

- defines how to document adherence to DICOMweb Storage Commitment in a DICOM Conformance Statement;
- defines two new attributes/tags (both SQ);
- comes with some examples.

Details

BI-DIRECTIONAL PROXYABILITY

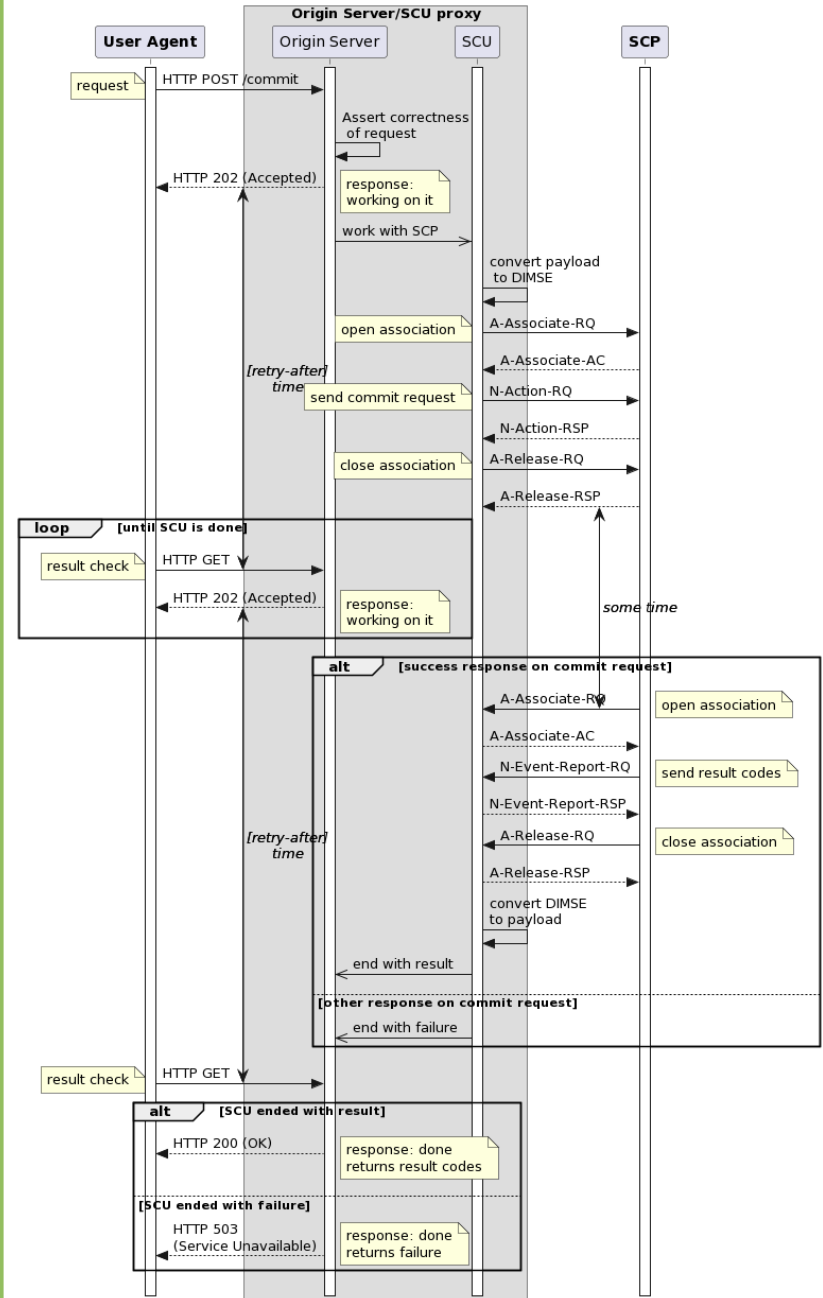

Bi-Directional Proxyability – Introduction

- The DICOMweb Storage Commitment Service may be deployed in a hybrid context, i.e. a context in which both DICOMweb and DIMSE are used.
- Therefore, bi-directional proxyability is important as to support whatever configuration of DICOM nodes.
- Next slide shows how to proxy from a DIMSE SCU to a DICOMweb Origin Server and from a DICOMweb User Agent to a DIMSE SCP.

DIMSE to DICOMweb
